

Registry:

"EngineCommand" - the prefix used to dispatch fscommands to the plug-in.

If the value is "myprefix:", then the command will have this form:
fscommand("exec","j::myprefix:TheCustomCommand");

"Parameter1", "Parameter2" and so on:

The caption label text used for the corresponding plug-in parameter.

Properties1, Properties2 and so on:

If there is a Properties1 text, the edit box for the first parameter will have ". . ." button for its properties.
The same for Properties2 etc. The text itself is not important so far, as the plug-in is called with the zero based index, not with this text.
But we recommend a meaning full value is used, such as "/filename", "/properties" etc.

"PlugIn" - must be '1'

Path - shows where the DLL for the plug-in is located.
